HANYANG UNIVERSITY

The Recursion Pattern

- **Recursion**: when a method calls itself
- Classic example--the factorial function:
  - n! = 1· 2· 3· ··· · (n-1)· n
- Recursive definition:

- As a Java method:

```
// recursive factorial function
public static int recursiveFactorial(int n) {
   if (n == 0) return 1;     // basis case
   else return (                          );      // recursive case
}
```

Content of a Recursive Method

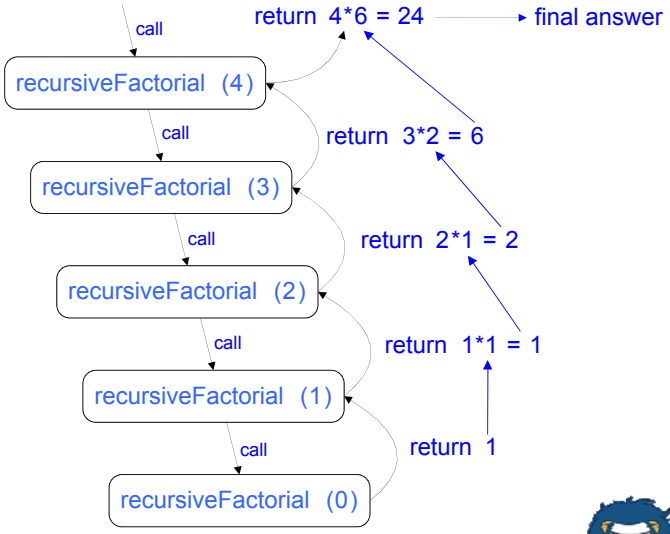
- Base case(s)
  - Values of the input variables for which we perform no recursive calls are called base cases (there should be at least one base case).
  - Every possible chain of recursive calls must eventually reach a base case.
- Recursive calls
  - Calls to the current method.
  - Each recursive call should be defined so that it makes progress towards a base case.

HANYANG UNIVERSITY

Visualizing Recursion

- Recursion trace
  - A box for each recursive call
  - An arrow from each caller to callee
  - An arrow from each callee to caller showing return value

- Example



HANYANG UNIVERSITY

Linear Recursion

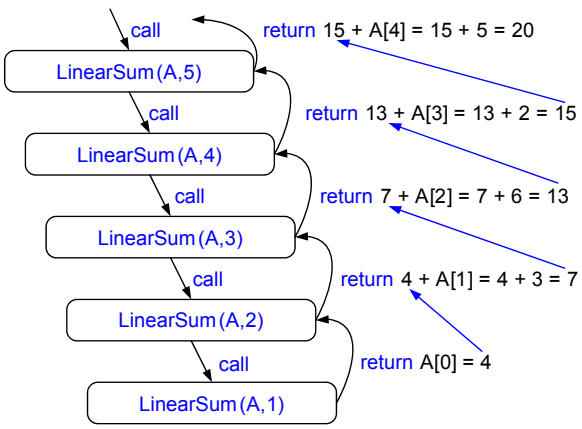
- Test for base cases
  - Begin by testing for a set of base cases (there should be at least one).
  - Every possible chain of recursive calls must eventually reach a base case, and the handling of each base case should not use recursion.
- Recur once
  - Perform a single recursive call
  - This step may have a test that decides which of several possible recursive calls to make, but it should ultimately make just one of these calls
  - Define each possible recursive call so that it makes progress towards a base case.

Example of Linear Recursion

Algorithm LinearSum(*A, n*):
Input:
A integer array *A* and an integer $n = 1$, such that *A* has at least *n* elements
Output:
The sum of the first *n* integers in *A*

```
if (          ) then
  return A[0]
else
  return  (                    )
```

Example recursion trace:



Reversing an Array

Algorithm ReverseArray(*A, i, j*):

Input: An array *A* and nonnegative integer indices *i* and *j*

Output: The reversal of the elements in *A* starting at index *i* and ending at *j*

if *i* < *j* **then**

Swap *A*[*i*] and *A*[*j*]

( )

return

Defining Arguments for Recursion

- In creating recursive methods, it is important to define the methods in ways that facilitate recursion.
- This sometimes requires we define additional paramaters that are passed to the method.
- For example, we defined the array reversal method as ReverseArray(*A, i, j*), not ReverseArray(*A*).

Computing Powers

- The power function, $p(x,n)=x^n$, can be defined recursively:

- This leads to an power function that runs in O(n) time (for we make n recursive calls).
- We can do better than this, however.

Recursive Squaring

- We can derive a more efficient linearly recursive algorithm by using repeated squaring:

$$p(x,n) = \begin{cases} 1 & \text{if } x = 0 \\ x \cdot p(x,(n-1)/2)^2 & \text{if } x > 0 \text{ is odd} \\ p(x,n/2)^2 & \text{if } x > 0 \text{ is even} \end{cases}$$

- For example,

$2^4 = 2^{(4/2)2} = (2^{4/2})^2 = (2^2)^2 = 4^2 = 16$

$2^5 = 2^{1+(4/2)2} = 2(2^{4/2})^2 = 2(2^2)^2 = 2(4^2) = 32$

$2^6 = 2^{(6/2)2} = (2^{6/2})^2 = (2^3)^2 = 8^2 = 64$

$2^7 = 2^{1+(6/2)2} = 2(2^{6/2})^2 = 2(2^3)^2 = 2(8^2) = 128.$

Recursive Squaring Method

Algorithm Power(x, n):
Input: A number x and integer $n = 0$
Output: The value x^n
if $n = 0$ **then**
return 1
if n is odd **then**
y = ( )
return $x \cdot y \cdot y$
else
y = ( )
return $y \cdot y$

Analysis

Algorithm Power(x, n):
Input: A number x and integer $n = 0$
Output: The value x^n
if $n = 0$ **then**
return 1
if n is odd **then**
y = Power(x, $(n - 1)/2$)
return $x \cdot y \cdot y$
else
y = Power(x, $n/2$)
return $y \cdot y$

Each time we make a recursive call we halve the value of n; hence, we make log n recursive calls. That is, this method runs in O(log n) time.

It is important that we use a variable twice here rather than calling the method twice.

Tail Recursion

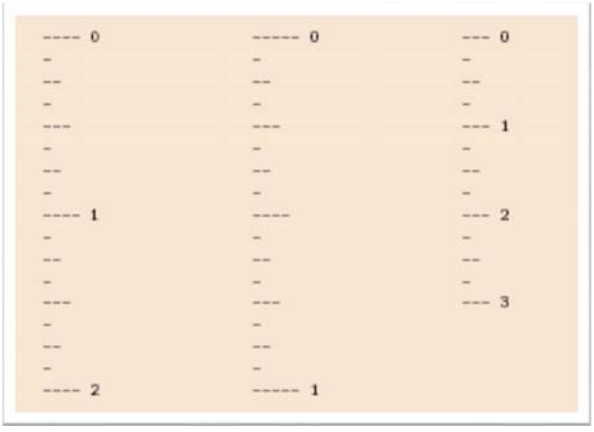
- Tail recursion occurs when a linearly recursive method makes its recursive call as its last step.
- The array reversal method is an example.
- Such methods can be easily converted to non-recursive methods (which saves on some resources).

- Example:

Algorithm IterativeReverseArray(*A*, *i*, *j*):
  Input: An array *A* and nonnegative integer indices *i* and *j*
  Output: The reversal of the elements in *A* starting at index *i* and ending at *j*
  while *i* < *j* **do**
    Swap *A*[*i*] and *A*[*j*]
    i = *i* + 1
    j = *j* - 1
  return

Binary Recursion

- Binary recursion occurs whenever there are **two** recursive calls for each non-base case.
- Example: the DrawTicks method for drawing ticks on an English ruler.

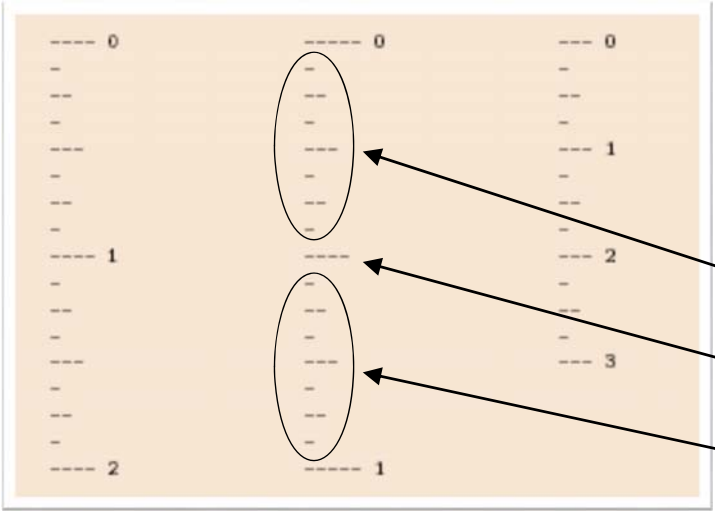


Using Recursion

drawTicks(length)

Input: length of a 'tick'

Output: ruler with tick of the given length in the middle and smaller rulers on either side



drawTicks(length)

if(length > 0) then

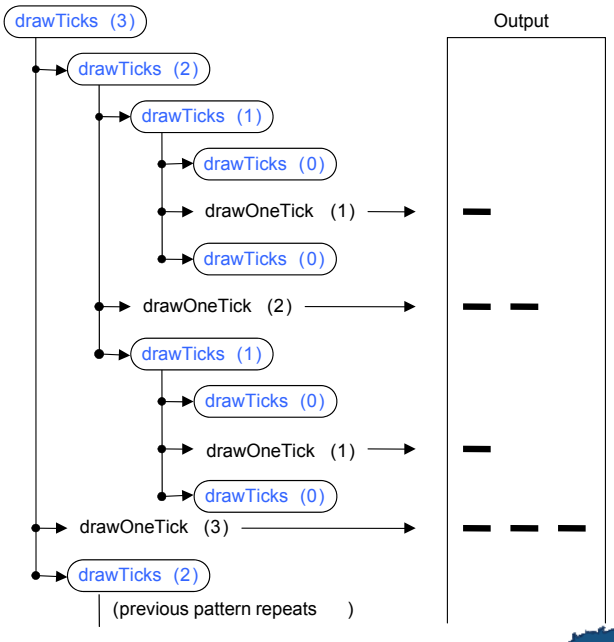
drawTicks(length – 1)

draw tick of the given length

drawTicks(length – 1)

Recursive Drawing Method

- The drawing method is based on the following recursive definition
- An interval with a central tick length L ≥1 consists of:
  - An interval with a central tick length L–1
  - An single tick of length L
  - An interval with a central tick length L–1



A Binary Recursive Method for Drawing Ticks

```
// draw a tick with no label
public static void drawOneTick(int tickLength) { drawOneTick(tickLength, - 1); }
// draw one tick
public static void drawOneTick(int tickLength, int tickLabel) {
   for (int i = 0; i < tickLength; i++)
      System.out.print("-");
   if (tickLabel >= 0) System.out.print(" " + tickLabel);
   System.out.print("\n");
}
// draw ticks of given length
public static void drawTicks(int tickLength) { // draw ticks of given length
   if (tickLength > 0) {                       // stop when length drops to 0
      drawTicks(tickLength- 1);     // recursively draw left ticks
      drawOneTick(tickLength);      // draw center tick
      drawTicks(tickLength- 1);     // recursively draw right ticks
   }
}
// draw ruler
public static void drawRuler(int nInches, int majorLength) { // draw ruler
   drawOneTick(majorLength, 0);  // draw tick 0 and its label
   for (int i = 1; i <= nInches; i++)              {
      drawTicks(majorLength- 1);   // draw ticks for this inch
      drawOneTick(majorLength, i);              // draw tick i and its label
   }
}
```

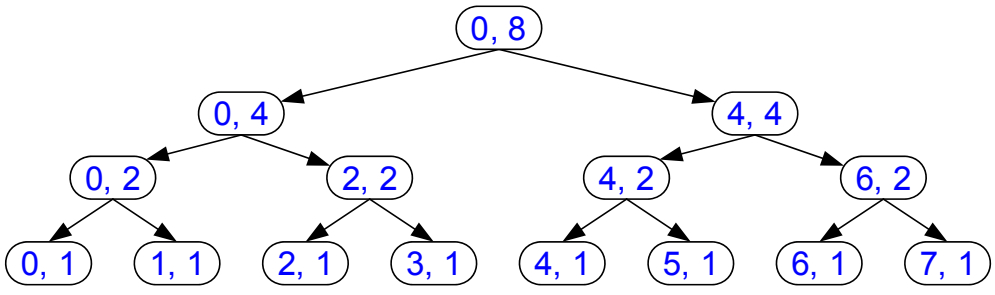
Note the two recursive calls

Another Binary Recursive Method

- Problem: add all the numbers in an integer array A:

  Algorithm BinarySum(*A, i, n*):
  Input: An array *A* and integers *i* and *n*
  Output: The sum of the *n* integers in *A* starting at index *i*
  if *n* = 1 **then**
  return *A*[*i*]
  return (**)**

- **Example trace:**



Computing Fibonacci Numbers

- Fibonacci numbers are defined recursively:

  $F_0 = 0$
  $F_1 = 1$
  $F_i = F_{i-1} + F_{i-2}$ for $i > 1$.

- Recursive algorithm (first attempt):

Algorithm BinaryFib(k):
  Input: Nonnegative integer k
  Output: The kth Fibonacci number F_k
 if $k = 1$ **then**
  return k
 else
  return (BinaryFib(k-1) + BinaryFib(k-2);)

Analysis

- Let n_k be the number of recursive calls by BinaryFib(k)
  - $n_0 = 1$
  - $n_1 = 1$
  - $n_2 = n_1 + n_0 + 1 = 1 + 1 + 1 = 3$
  - $n_3 = n_2 + n_1 + 1 = 3 + 1 + 1 = 5$
  - $n_4 = n_3 + n_2 + 1 = 5 + 3 + 1 = 9$
  - $n_5 = n_4 + n_3 + 1 = 9 + 5 + 1 = 15$
  - $n_6 = n_5 + n_4 + 1 = 15 + 9 + 1 = 25$
  - $n_7 = n_6 + n_5 + 1 = 25 + 15 + 1 = 41$
  - $n_8 = n_7 + n_6 + 1 = 41 + 25 + 1 = 67$.
- Note that n_k at least doubles every other time
- That is, $n_k > 2^{k/2}$. It is exponential!

A Better Fibonacci Algorithm

- Use linear recursion instead

```
Algorithm LinearFibonacci(k):
  Input: A nonnegative integer k
  Output: Pair of Fibonacci numbers (F_k , F_{k–1})
 if   k>1   then
     return  (LinearFibonacci(k-1) )
 else
     (i,  j)  = (            (j,i+k)            )
     return (          i          )
```

- LinearFibonacci makes k–1 recursive calls

Multiple Recursion

- Motivating example:
  - summation puzzles
    - *pot* + *pan* = *bib*
    - *dog* + *cat* = *pig*
    - *boy* + *girl* = *baby*
- Multiple recursion:
  - makes potentially many recursive calls
  - not just one or two

Algorithm for Multiple Recursion

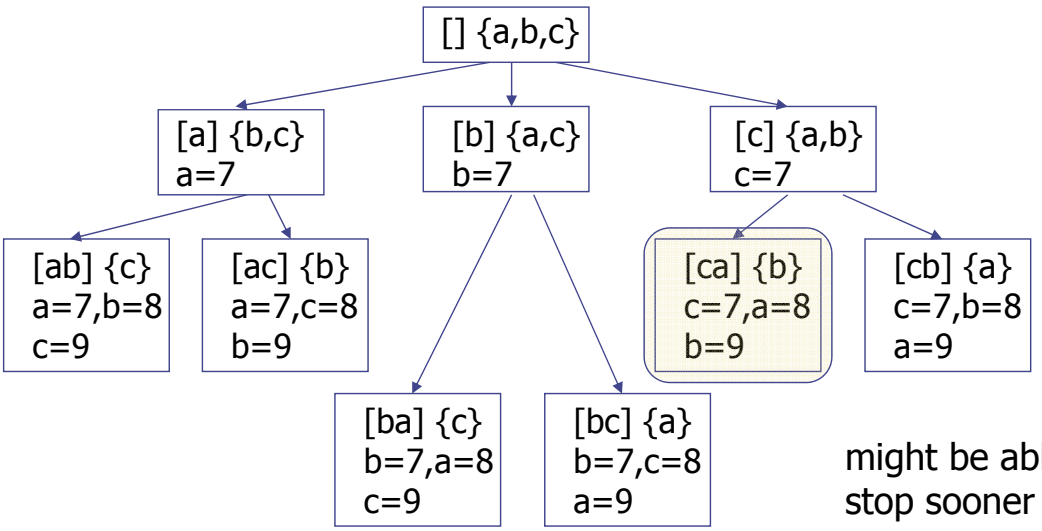
```
Algorithm PuzzleSolve(k,S,U):
 Input: Integer k, sequence S, and set U (universe of elements to test)
 Output:  Enumeration of all k-length extensions to S using elements
    in U without repetitions
 for all e  in U do
    Remove e from U      {e is now being used}
    Add e to the end of S
    if k = 1 then
          Test whether S is a configuration that solves the puzzle
          if S solves the puzzle then
                return "Solution found: " S
    else
          PuzzleSolve(k - 1, S,U)
    Add e back to U       {e is now unused}
    Remove e from the end of S
```

Example

cbb + ba = abc

799 + 98 = 997

a,b,c stand for 7,8,9; not necessarily in that order



might be able to stop sooner
