9.1: Global DOM Objects

- 9.1: Global DOM Objects
- 9.2: The DOM Tree

The six global DOM objects

Every Javascript program can refer to the following global objects:

name	description
document	current HTML page and its content
history	list of pages the user has visited
location	URL of the current HTML page
navigator	info about the web browser you are using
screen	info about the screen area occupied by the browser
window	the browser window

The [window](#) object

the entire browser window; the top-level object in DOM hierarchy

- technically, all global code and variables become part of the window object
- properties:
 - [document](#), [history](#), [location](#), [name](#)
- methods:
 - [alert](#), [confirm](#), [prompt](#) (popup boxes)
 - [setInterval](#), [setTimeout](#), [clearInterval](#), [clearTimeout](#) (timers)
 - [open](#), [close](#) (popping up new browser windows)
 - [blur](#), [focus](#), [moveBy](#), [moveTo](#), [print](#), [resizeBy](#), [resizeTo](#), [scrollBy](#), [scrollTo](#)

Popup windows with `window.open`

```
window.open("http://foo.com/bar.html", "My Foo Window",  
            "width=900,height=600,scrollbars=1");
```

JS

- `window.open` pops up a new browser window
- THIS method is the cause of all the terrible popups on the web!
- some popup blocker software will prevent this method from running

The `document` object

the current web page and the elements inside it

- properties:
 - `anchors`, `body`, `cookie`, `domain`, `forms`, `images`, `links`, `referrer`, `title`, `URL`
- methods:
 - `getElementById`
 - `getElementsByName`
 - `getElementsByTagName`
 - `close`, `open`, `write`, `writeln`
- complete list

The **location** object

the URL of the current web page

- properties:
 - `host`, `hostname`, `href`, `pathname`, `port`, `protocol`, `search`
- methods:
 - `assign`, `reload`, `replace`
- `complete` list

The **navigator** object

information about the web browser application

- properties:
 - `appName`, `appVersion`, `language`, `cookieEnabled`, `platform`, `userAgent`
 - `complete` list
- Some web programmers examine the navigator object to see what browser is being used, and write browser-specific scripts and hacks:

```
if (navigator.appName === "Microsoft Internet Explorer") { ...
```

JS

- (this is poor style; you should not need to do this)

The **screen** object

information about the client's display screen

- properties:
 - `availHeight`, `availWidth`, `colorDepth`, `height`, `pixelDepth`, `width`
 - [complete list](#)

The **history** object

the list of sites the browser has visited in this window

- properties:
 - `length`
- methods:
 - `back`, `forward`, `go`
- [complete list](#)
- sometimes the browser won't let scripts view `history` properties, for security

Unobtrusive JavaScript

- JavaScript event code seen previously was *obtrusive*, in the HTML; this is bad style
- now we'll see how to write *unobtrusive JavaScript* code
 - HTML with minimal JavaScript inside
 - uses the DOM to attach and execute all JavaScript functions
- allows *separation* of web site into 3 major categories:
 - **content** (HTML) - what is it?
 - **presentation** (CSS) - how does it look?
 - **behavior** (JavaScript) - how does it respond to user interaction?

Obtrusive event handlers (bad)

<code><button onclick="okayClick();">OK</button></code>	HTML
<pre>// called when OK button is clicked function okayClick() { alert("booyah"); }</pre>	JS
<div>OK</div>	output

- this is bad style (HTML is cluttered with JS code)
- goal: remove all JavaScript code from the HTML body

Attaching an event handler in JavaScript code

```
// where element is a DOM element object
element.onclick = function; JS
```

```
<button id="ok">OK</button> HTML
```

```
var okButton = document.getElementById("ok");
okButton.onclick = okayClick; JS
```

```
OK output
```

- it is legal to attach event handlers to elements' DOM objects in your JavaScript code
 - notice that you do **not** put parentheses after the function's name
- this is better style than attaching them in the HTML
- Where should we put the above code?

When does my code run?

```
<html>
  <head>
    <script src="myfile.js" type="text/javascript"></script>
  </head>
  <body> ... </body> </html>
```

HTML

```
// global code
var x = 3;
function f(n) { return n + 1; }
function g(n) { return n - 1; }
x = f(x);
```

JS

- your file's JS code runs the moment the browser loads the `script` tag
 - any variables are declared immediately
 - any functions are declared but not called, unless your global code explicitly calls them
- at this point in time, the browser has not yet read your page's body
 - none of the DOM objects for tags on the page have been created yet

A failed attempt at being unobtrusive

```
<html>
  <head>
    <script src="myfile.js" type="text/javascript"></script>
  </head>
  <body>
    <div><button id="ok">OK</button></div>
```

HTML

```
// global code
document.getElementById("ok").onclick = okayClick; // error: null
```

JS

- problem: global JS code runs the moment the script is loaded
- script in head is processed before page's body has loaded
 - no elements are available yet or can be accessed yet via the DOM
- we need a way to attach the handler after the page has loaded...

The window.onload event

```
// this will run once the page has finished loading
function functionName() {
  element.event = functionName;
  element.event = functionName;
  ...
}
```

```
window.onload = functionName; // global code
```

JS

- we want to attach our event handlers right after the page is done loading
 - there is a global event called window.onload event that occurs at that moment
- in window.onload handler we attach all the other handlers to run when events occur

An unobtrusive event handler

<button id="ok">OK</button> <!-- look Ma, no JavaScript! -->

// called when page loads; sets up event handlers
function pageLoad() {
 document.getElementById("ok").onclick = okayClick;
}

function okayClick() {
 alert("booyah");
}

window.onload = pageLoad; // global code

HTML

JS

output

OK

Common unobtrusive JS errors

- many students mistakenly write () when attaching the handler

```
window.onload = pageLoad( );  
window.onload = pageLoad;  
  
okButton.onclick = okayClick( );  
okButton.onclick = okayClick;
```

JS

- our **JSLint** checker will catch this mistake
- event names are all lowercase, not capitalized like most variables

```
window.onLoad = pageLoad;  
window.onload = pageLoad;
```

JS

Anonymous functions

```
function(parameters) {  
    statements;  
}
```

JS

- JavaScript allows you to declare **anonymous functions**
- quickly creates a function without giving it a name
- can be stored as a variable, attached as an event handler, etc.

Anonymous function example

```
window.onload = function() {  
    var okButton = document.getElementById("ok");  
    okButton.onclick = okayClick;  
};  
  
function okayClick() {  
    alert("booyah");  
}
```

JS

OK

output

- or the following is also legal (though harder to read and bad style):

```
window.onload = function() {  
    var okButton = document.getElementById("ok");  
    okButton.onclick = function() {  
        alert("booyah");  
    };  
};
```

JS

Unobtrusive styling

```
function okayClick() {  
    this.style.color = "red";  
    this.className = "highlighted";  
}
```

JS

```
.highlighted { color: red; }
```

CSS

- well-written JavaScript code should contain as little CSS as possible
- use JS to set CSS classes/IDs on elements
- define the styles of those classes/IDs in your CSS file

9.2: The Dom Tree

- 9.1: Global DOM Objects
- **9.2: The DOM Tree**

Complex DOM manipulation problems

How would we do each of the following in JavaScript code? Each involves modifying each one of a group of elements ...

- When the Go button is clicked, reposition all the `divs` of class `puzzle` to random x/y locations.
- When the user hovers over the maze boundary, turn all maze walls red.
- Change every other item in the `ul` list with `id` of `TAs` to have a gray background.

The DOM tree

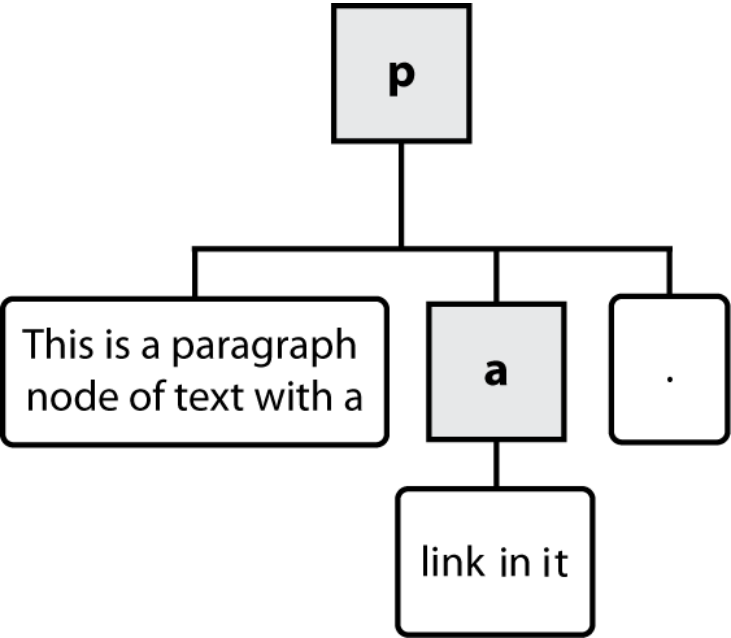

- The elements of a page are nested into a tree-like structure of objects
 - the DOM has properties and methods for traversing this tree

Types of DOM nodes

```
<p>
  This is a paragraph of text with a
  <a href="/path/page.html">link in it</a>.
</p>
```

HTML

-  **element nodes** (HTML tag)
 - can have children and/or attributes
-  **text nodes** (text in a block element)
-  **attribute nodes** (attribute/value pair)
 - text/attributes are children in an element node
 - cannot have children or attributes
 - not usually shown when drawing the DOM tree

Traversing the DOM tree

every node's DOM object has the following properties:

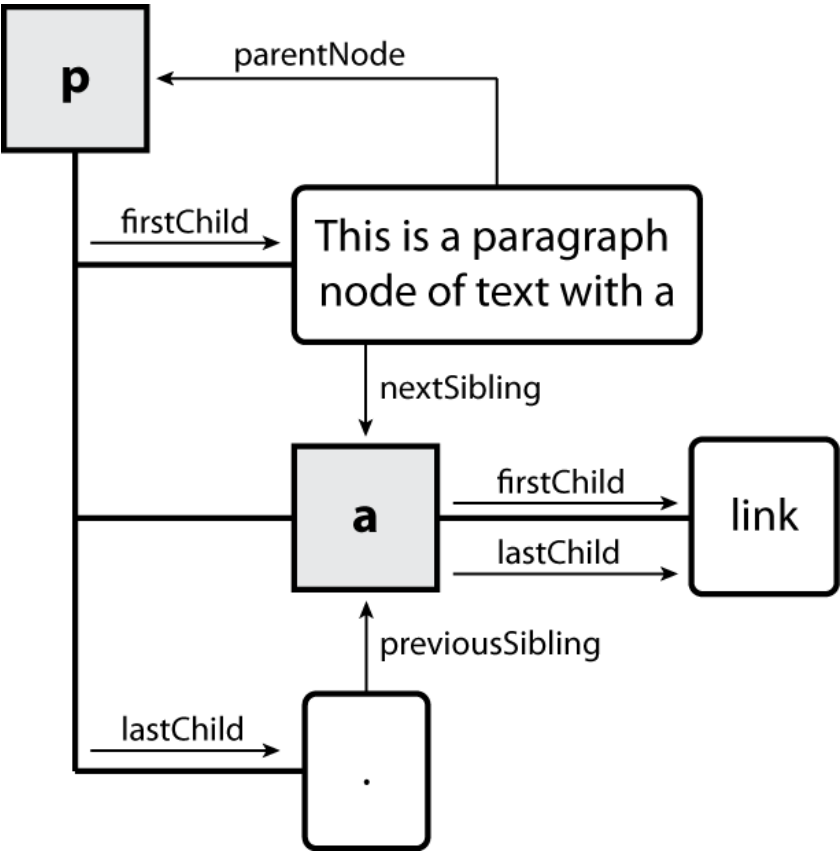

name(s)	description
firstChild, lastChild	start/end of this node's list of children
childNodes	array of all this node's children
nextSibling, previousSibling	neighboring nodes with the same parent
parentNode	the element that contains this node

- [complete list of DOM node properties](#)
- [browser incompatiblity information](#) (IE6 sucks)

DOM tree traversal example

```
<p id="foo">This is a paragraph of text with a  
  <a href="/path/to/another/page.html">link</a>.</p>
```

HTML

Element vs. text nodes

```
<div>
  <p>
    This is a paragraph of text with a
    <a href="page.html">link</a>.
  </p>
</div>
```

HTML

- Q: How many children does the `div` above have?
- A: 3
 - an element node representing the `<p>`
 - two *text nodes* representing "`\n\t`" (before/after the paragraph)
- Q: How many children does the paragraph have? The `a` tag?

Selecting groups of DOM objects

- methods in document and other DOM objects (* = HTML5):

name	description
<code>getElementsByTagName</code>	returns array of descendents with the given tag, such as "div"
<code>getElementsByName</code>	returns array of descendents with the given name attribute (mostly useful for accessing form controls)
<code>querySelector</code> *	returns the first element that would be matched by the given CSS selector string
<code>querySelectorAll</code> *	returns an array of all elements that would be matched by the given CSS selector string

Getting all elements of a certain type

highlight all paragraphs in the document:

```
var allParas = document.querySelectorAll("p");
for (var i = 0; i < allParas.length; i++) {
    allParas[i].style.backgroundColor = "yellow";
}
```

JS

```
<body>
  <p>This is the first paragraph</p>
  <p>This is the second paragraph</p>
  <p>You get the idea...</p>
</body>
```

HTML

Complex selectors

highlight all paragraphs inside of the section with ID "address":

```
// var addrParas = document.getElementById("address").getElementsByTagName("p");
var addrParas = document.querySelectorAll("#address p");
for (var i = 0; i < addrParas.length; i++) {
  addrParas[i].style.backgroundColor = "yellow";
}
```

JS

```
<p>This won't be returned!</p>
<div id="address">
  <p>1234 Street</p>
  <p>Atlanta, GA</p>
</div>
```

HTML

Creating new nodes

name	description
document.createElement(" <i>tag</i> ")	creates and returns a new empty DOM node representing an element of that type
document.createTextNode(" <i>text</i> ")	creates and returns a text node containing given text

```
// create a new <h2> node
var newHeading = document.createElement("h2");
newHeading.innerHTML = "This is a heading";
newHeading.style.color = "green";
```

JS

- merely creating a node does not add it to the page
- you must add the new node as a child of an existing element on the page...

Modifying the DOM tree

Every DOM element object has these methods:

name	description
<code>appendChild(<i>node</i>)</code>	places given node at end of this node's child list
<code>insertBefore(<i>new</i>, <i>old</i>)</code>	places the given new node in this node's child list just before <code>old</code> child
<code>removeChild(<i>node</i>)</code>	removes given node from this node's child list
<code>replaceChild(<i>new</i>, <i>old</i>)</code>	replaces given child with new node

```
var p = document.getElementById(document.createElement("p"));
p.innerHTML = "A paragraph!";
document.getElementById("main").appendChild(p);
```

JS

Removing a node from the page

```
function slideClick() {
  var bullets = document.getElementsByTagName("li");
  for (var i = 0; i < bullets.length; i++) {
    if (bullets[i].innerHTML.indexOf("children") >= 0) {
      bullets[i].parentNode.removeChild(bullets[i]);
    }
  }
}
```

JS

- each DOM object has a `removeChild` method to remove its children from the page

DOM versus **innerHTML** hacking

Why not just code the previous example this way?

```
function slideClick() {  
    document.getElementById("thisslide").innerHTML += "<p>A paragraph!</p>";  
}
```

JS

- Imagine that the new node is more complex:
 - ugly: bad style on many levels (e.g. JS code embedded within HTML)
 - error-prone: must carefully distinguish " and '
 - can only add at beginning or end, not in middle of child list

```
function slideClick() {  
    this.innerHTML += "<p style='color: red; " +  
        "margin-left: 50px;' " +  
        "onclick='myOnClick();'>" +  
        "A paragraph!</p>";  
}
```

JS
